## ABSTRACT

This publication contains areally-averaged temperature data for the conterminous United States and nine climatologically-defined groups of states (i.e., regions), for the 89-year period, 1895 through 1983. Tabular listings give the average temperatures by month, and groups of months (which includes the seasons and year) for the individual years in the period of record. The rank of the year-value of the calendar event is also given, which facilitates the identification of inter-annual, intra-annual, and intra-seasonal climate variability. Time series plots of annual mean temperatures for the nation and each region depict the inter-annual variation about the long-term (1895-1983) mean temperature.

The data presented in this publication are available in digital form on magnetic tape and/or floppy disk, and can be purchased by written order from:

National Climatic Data Center  
Federal Building  
Asheville, NC 28801-2696

or, by calling (704) 259-0682 (FTS 672-0682).

## 1. INTRODUCTION

Climate can be thought of as a part of our natural environment, hence changes in climate have a direct effect on the environment's ecosystem. Often the ecosystem itself is considered to be in a state of "dynamic equilibrium" with the climate, where the ecosystem is constantly striving to respond to changes in climatic factors such as temperature, precipitation, etc. For example, vegetation and water supply often respond to the "normal" annual cycles of temperature and precipitation in a fairly predictable manner, but abnormalities in those cycles often result in unexpected departures from an equilibrium condition. Knowingly or not, society has developed various socioeconomic activities based on the response of the ecosystem to the climate. A few examples of such activities are the building of dams and reservoirs, irrigation farming, the scheduling of sporting events, the development of retail and wholesale trade strategies, and the many facets of architectural design. Also, when the ecosystem responds to climate-induced stress (a significant climate anomaly), considerable human hardship and even loss of life can ensue. As an example, during lengthy periods of much above average temperatures, both man and his environment usually suffer dire consequences because of elevated levels of heat stress. The use of quantitative historical climate data, whereby each climate anomaly (the departure of the climate from some established normal value) can be put into historical perspective, allows society to develop rational plans and make sound operational decisions which might anticipate and mitigate the effects of these anomalies on human welfare. Such a need for historical temperature data has resulted in the addition of this publication to the National Climatic Data Center's (NCDC) Historical Climatology Series (HCS).

The data summaries in this publication differ significantly, in some respects, from those given in HCS 4-1, State, Regional, and National Monthly and Annual Temperatures Weighted by Area (January 1931-December 1982). The differences are:

- a. The period of record for HCS 4-1 is 1931 through 1982 (52 years), whereas this publication contains data for the 89-year period, 1895-1983.
- b. This publication does not contain individual state data.
- c. This publication contains month-grouped data which includes the usual seasonal monthly groups: Winter (December-February), Spring (March-May), Summer (June-August), and Fall (September-November).
- d. The rank order in this publication is opposite to that given in HCS 4-1; i.e., here the number one rank is the coldest temperature, whereas in HCS 4-1 it is the warmest temperature.
- e. The definitions of the regions, in terms of specific groupings of contiguous states, differ significantly. In HCS 4-1 the regions are the nine census regions as defined and used by the Bureau of the Census; in this publication the nine regions are climatologically-defined groups of adjoining states (Karl and Koscielny, 1982) which were shown to be climatically similar during the period 1895-1981.

USERS OF THESE DATA FOR THE YEARS PRIOR TO 1931 IN THE MOUNTAINOUS WESTERN REGIONS SHOULD BE AWARE THAT THE SPATIAL DISTRIBUTION OF STATIONS WITHIN THOSE REGIONS HAS NOT BEEN HOMOGENEOUS. AS A RESULT, THE DATA DURING THE EARLY PORTION OF RECORD SHOULD BE VIEWED WITH CAUTION. SECTION 2(b) DESCRIBES THIS PROBLEM IN MORE DETAIL.

## 2. DATA DESCRIPTIONS

The regional and national average temperatures given in this publication are based on divisional and statewide data which are described below.

### a. State Climatic Divisional Data

The NCDC maintains and routinely publishes monthly averages of temperature for state climatic divisions in the publication, Climatological Data (U.S. Department of Agriculture, 1931-40; U.S. Department of Commerce, 1940-84). A climatic division represents a region within a state that is, as nearly as possible, climatically homogeneous. Obviously, within a division having complex terrain rather extreme temperature variations can routinely occur, but usually the standardized departures from normal are spatially consistent within a division. Since 1931, each monthly average temperature within a division has been calculated by giving equal weight to each station reporting temperature within a division. The number of stations within a division varies over time as stations open and close. By using many stations within a division to calculate averages, this potential source of bias is minimized. Nonetheless, for those divisions with complex terrain and few continuously operating stations, caution should be exercised, especially by those interested in small differences for applications or for climatic change. In 1984, approximately 5,000 stations were used to calculate the divisional averages in the contiguous United States.

### b. Statewide Data

Monthly averages of temperature have been calculated across all 48 contiguous states for periods dating back to the nineteenth century. Since 1931, statewide averages have been calculated by areally weighing the divisional temperature averages; prior to 1931, statewide averages were estimated from data compiled by the U.S. Department of Agriculture (USDA, 1951). The USDA (1951) published state averages of temperature from the late 1800s through 1948. Those averages were obtained by equally weighting all available reporting stations within a state. The average monthly temperature data, as published by the USDA (1951), were compared with the state averages from the divisional data during the overlap period (1931-1948). The USDA's (1951) published values were then adjusted to more closely resemble the state averages obtained from areally-weighted divisional data. For each month, the average difference in temperature between the two overlapping periods were used to adjust the pre-1931 temperature data. After the adjustment, the correlation between the two data sets for each state and month was excellent ( $> 0.90$ , Diaz and Quayle, 1978).

In New England the USDA (1951) had combined the states of Maine, New Hampshire, and Vermont into Northern New England; and Connecticut, Massachusetts, and Rhode Island into Southern New England. For that reason it was necessary to use the divisional averages of temperature as they appeared in the Climatological Data (U.S. Department of Agriculture, 1895-1930). These divisional averages were then areally weighted to obtain state averages. In California the earliest published (USDA, 1951) data began in January 1897. For the years 1895 and 1896, monthly estimates of statewide averages of temperature were obtained by constructing isopleth analyses of the monthly station data.

In spite of the excellent correlation between the statewide average data derived from the state climate divisions and the USDA's published data during the overlap period, there were still some unrealistically large serially correlated departures from normal during the early portion of the period of record in some of the mountainous western states (Arizona, in particular). This is attributed to the fact that during the early period of record some of the western states had relatively few stations in unsettled areas of the state. For example, in January 1900 only 10% of the stations in Arizona were located north of the 35th parallel (approximately the northern half of the state), and well over half of the stations were located in the southeast quarter of the state (U.S. Department of Commerce, 1958). As new stations were added in areas which previously had relatively few stations and, thus, had little weight in the state average (prior to 1931), an apparent change in climate was introduced into the time series. In order to correct this problem, the pre-1931 temperature data sets were adjusted a second time for the 11 western states from Montana to New Mexico and west to the Pacific Ocean. Monthly adjustments were applied to each state based on the seasonal departure from average of the mean difference of the statewide seasonal average from the USDA's published data ( $U_j$ ) and another statewide seasonal average derived from a fixed number of stations ( $F_j$ ) spatially distributed as evenly as possible across each state. The seasonal average difference ( $D_j$ ) is defined as:

$$D_j = \frac{\sum_{i=1}^N (U_{i,j} - F_{i,j})}{N} \cdot (N)^{-1} \quad (1)$$

where  $j$  is one of the four seasons (winter is defined as January through March; spring, April through June, etc.) and  $N$  is the number of coincident years prior to 1931 in the two data sets. The magnitude and sign of the adjustment is determined for each season of a given year by:

$$A_{j,i} = D_j - (U_{j,k} - F_{j,i}) \quad (2)$$

and the final adjusted monthly (mo) value is given by:

$$U_{mo,i} = U_{mo,i} + A_{j,i} \quad (3)$$

if

$$A_{j,i} > 0.25^{\circ}\text{F} \quad (4)$$

otherwise no adjustment is applied. The threshold value in (4) was chosen on the basis of subjective estimates of the year-to-year variability of  $D_j$ , not associated with any linear trends as depicted in time series plots.

For each state,  $U_{mo,i}$  extended further back in time than  $F_{mo,i}$ . For those years, an average of the first five years of coincident data were used to obtain the term  $(U_{j,i} - F_{j,i})$  in (2) and, subsequently, the adjustment  $A_{j,i}$  was applied to the remaining data ( $U_{mo,i}$ ) when the relational test (4) was true. Therefore, during those years, the data should be used with caution. The beginning dates of the fixed network for each of the 11 western states is listed below:

Arizona	1904
California	1895
Colorado	1903
Idaho	1909
Montana	1906
Nevada	1913
New Mexico	1900
Oregon	1903
Utah	1914
Washington	none
Wyoming	1905

#### c. Regional and National Data

The regional and national data in this publication are areally-averaged division/statewide data, which were described in the preceding sections. The regional subdivisions of the conterminous United States are based on climatological analyses which considered the temporal and spatial temperature and precipitation distributions for groups of contiguous states; the composition of the regions and the areal weights, which were used in obtaining the areal average temperatures, are given on page 6. A map, which shows the regional divisions, is on page 7. Karl and Koscielny (1982) give the reasoning and techniques for the regional classification in their analyses of drought data for the long-term period 1895-1981. This classification is better suited for climatological use than is the Bureau of the Census regional grouping of states, which is somewhat deficient in defining climatic sections of the United States. Caution must be used when comparing regional data in this publication with that from other sources because of possible differences in the definition of the regions.

### 3. DATA PRESENTATIONS

#### a. Table Listings

There are two types of table listings, monthly and "seasonal" (i.e., month-group). In the seasonal table listings averages of temperature pertain to the months indicated; i.e., Jun-Sep denotes the months of June, July, August, and September. When the season overlaps calendar years, then the season is listed with the earlier year; i.e., Dec-Feb of 1956 denotes December 1956, January 1957, and February 1957.

In each table the rank associated with the reported value is indicated to the right of the '/'. The values are ranked from lowest to highest. At the bottom of each table are summary statistics:

- (1) MAX - This row contains the highest reported value within each month or season.
- (2) MIN - This row contains the lowest reported value for each month or season.
- (3) AVE - This row contains the average value for each month or season.
- (4) STDEV - This row contains the standard deviation for each month or season.
- (5) 5TH% - This row contains the value associated with the percentile nearest to the fifth percentile for each month or season.
- (6) 95TH% - This row contains the value associated with the percentile nearest to the ninety-fifth percentile for each month or season.
- (7) #YRS - This row contains the number of years of data within each column.

#### b. Time Series Plots

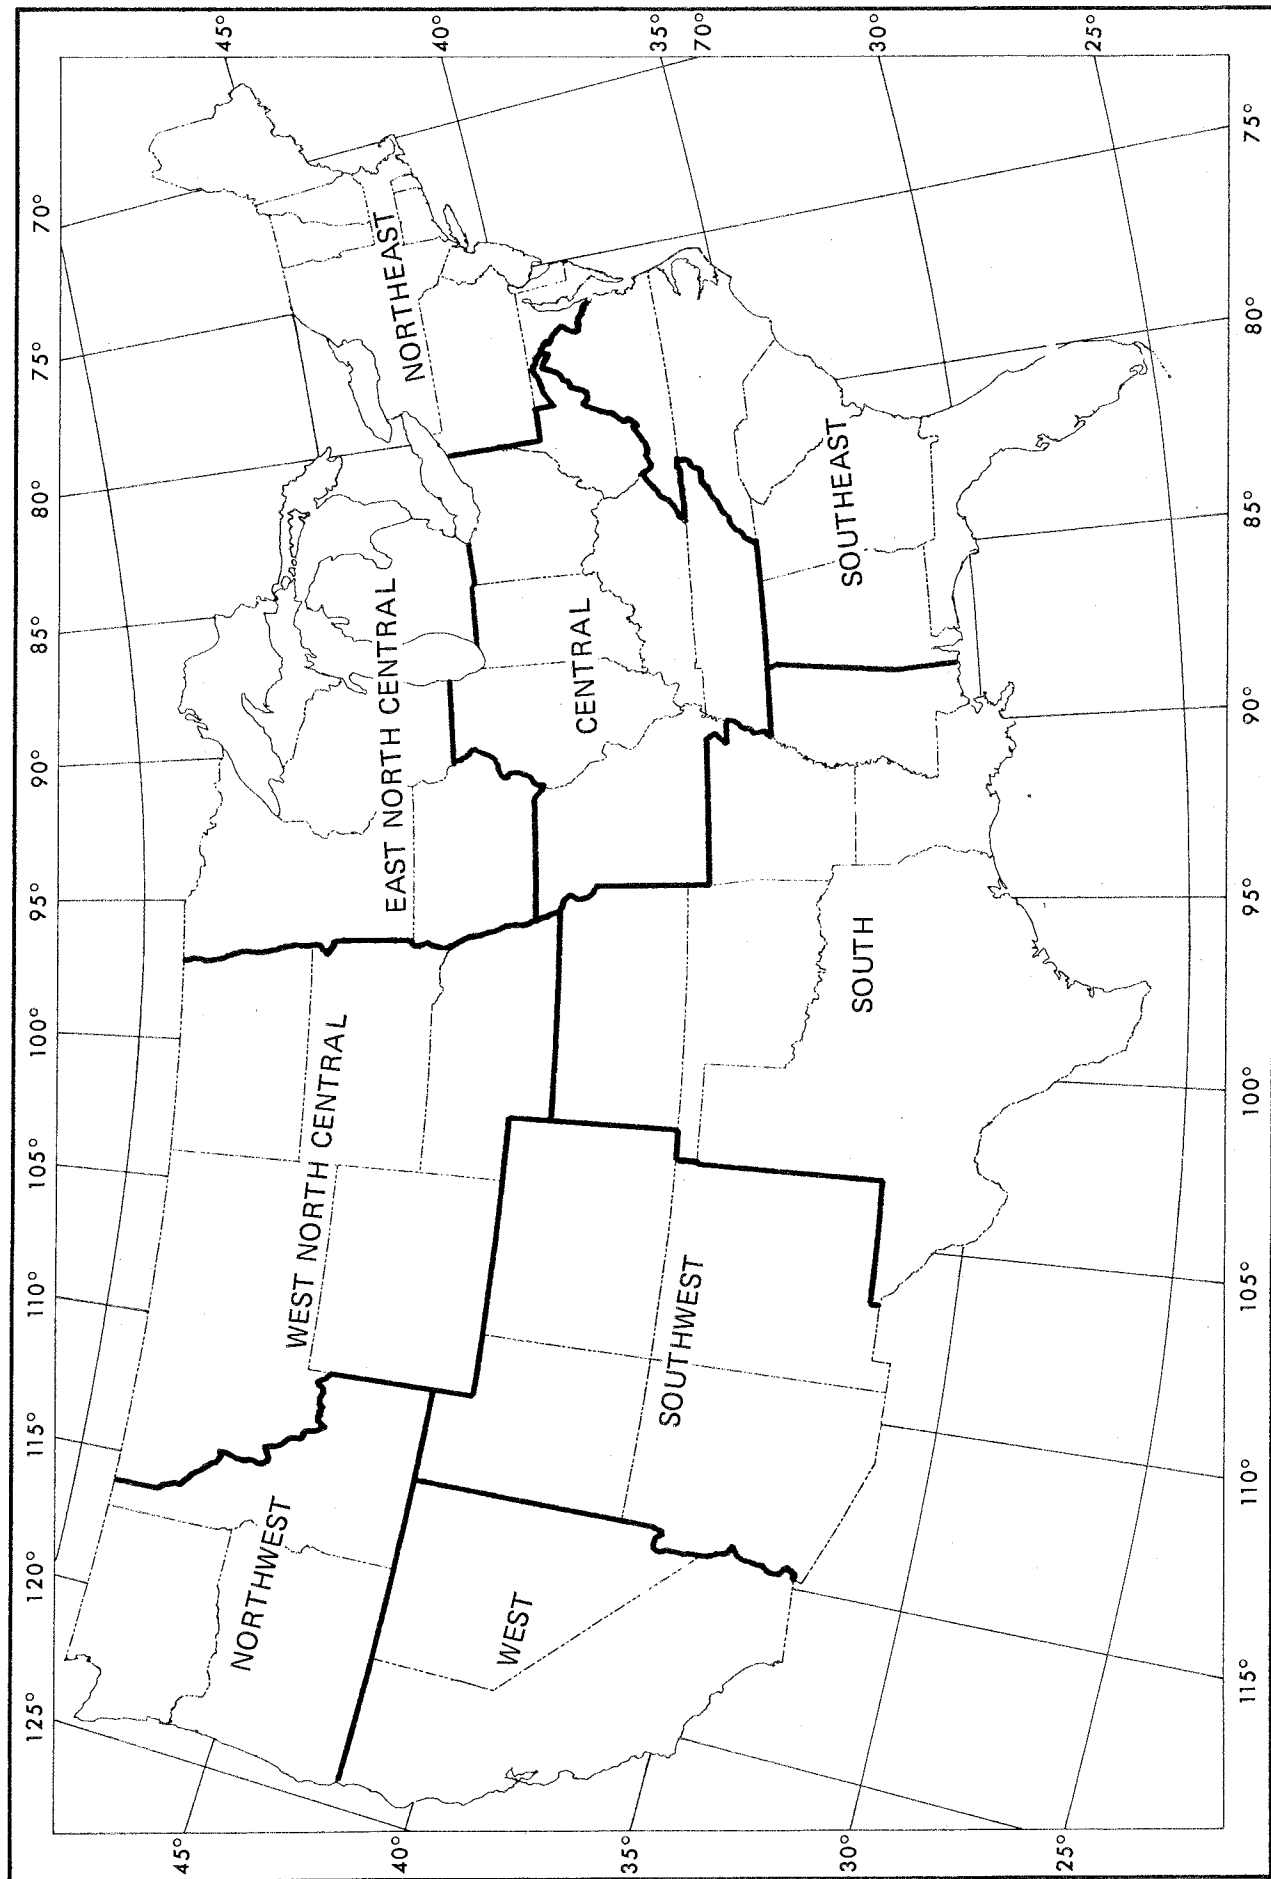

For the period of record specified on the plot, the mean is indicated by a horizontal dashed line. The actual values as reported are indicated by asterisks and are connected by straight lines (the mean temperatures are posted to tenths of a degree Fahrenheit (°F)).
